ssoloway@drsoloway.com

A 44-YEAR-OLD MAN PRESENTED TO THE RHEUMATOLOGY CLINIC WITH A 5-year history of heat intolerance and burning pain in his hands and feet. He also had exertional dyspnea, decreased perspiration, sinus tachycardia, and proteinuria of unclear cause. On physical examination, there were periumbilical vascular skin lesions that had been present for the previous 20 years (Panel A), a finding consistent with angiokeratomas. A sample from a 24-hour urine collection showed nonnephrotic proteinuria. Light microscopy of a sample of kidney tissue was notable for focally swollen podocytes with vacuolated cytoplasm. Electron microscopy showed lamellated deposits typical of globotriaosylceramide in podocytes, a finding known as zebra bodies that is characteristic of Fabry's disease (Panel B). A leukocyte assay showed that α-galactosidase A activity was less than 1.0 nmol per hour per milligram of protein (reference range, 45 to 85). Genetic testing identified a variant in *GLA*. A diagnosis of Fabry's disease was made. Fabry's disease is an X-linked lysosomal storage disease characterized by a deficiency in α-galactosidase A, a lysosomal hydrolase enzyme. The resulting accumulation of glycosphingolipids within cells leads to various symptoms, including neuropathy, autonomic dysfunction, hypohidrosis, skin lesions, and proteinuria (as seen in this patient). Genetic testing of the patient's family identified the *GLA* variant in his mother and brother. Treatment with enzyme-replacement therapy was started, and referral was made to neurology, nephrology, and cardiology specialists for cardiac evaluation and long-term management of the condition.

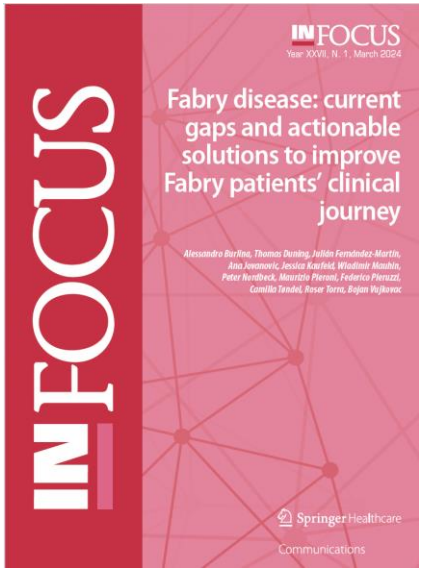

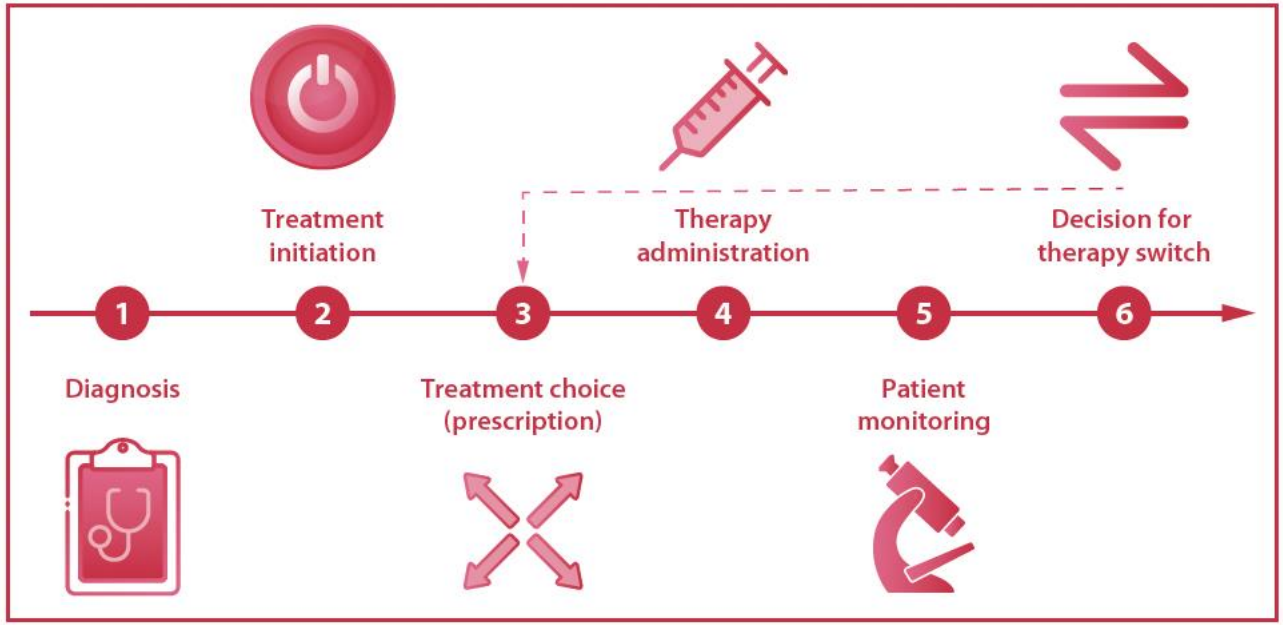

Figure 1. The six main steps in the specialists' journey in FD (Fabry Disease)

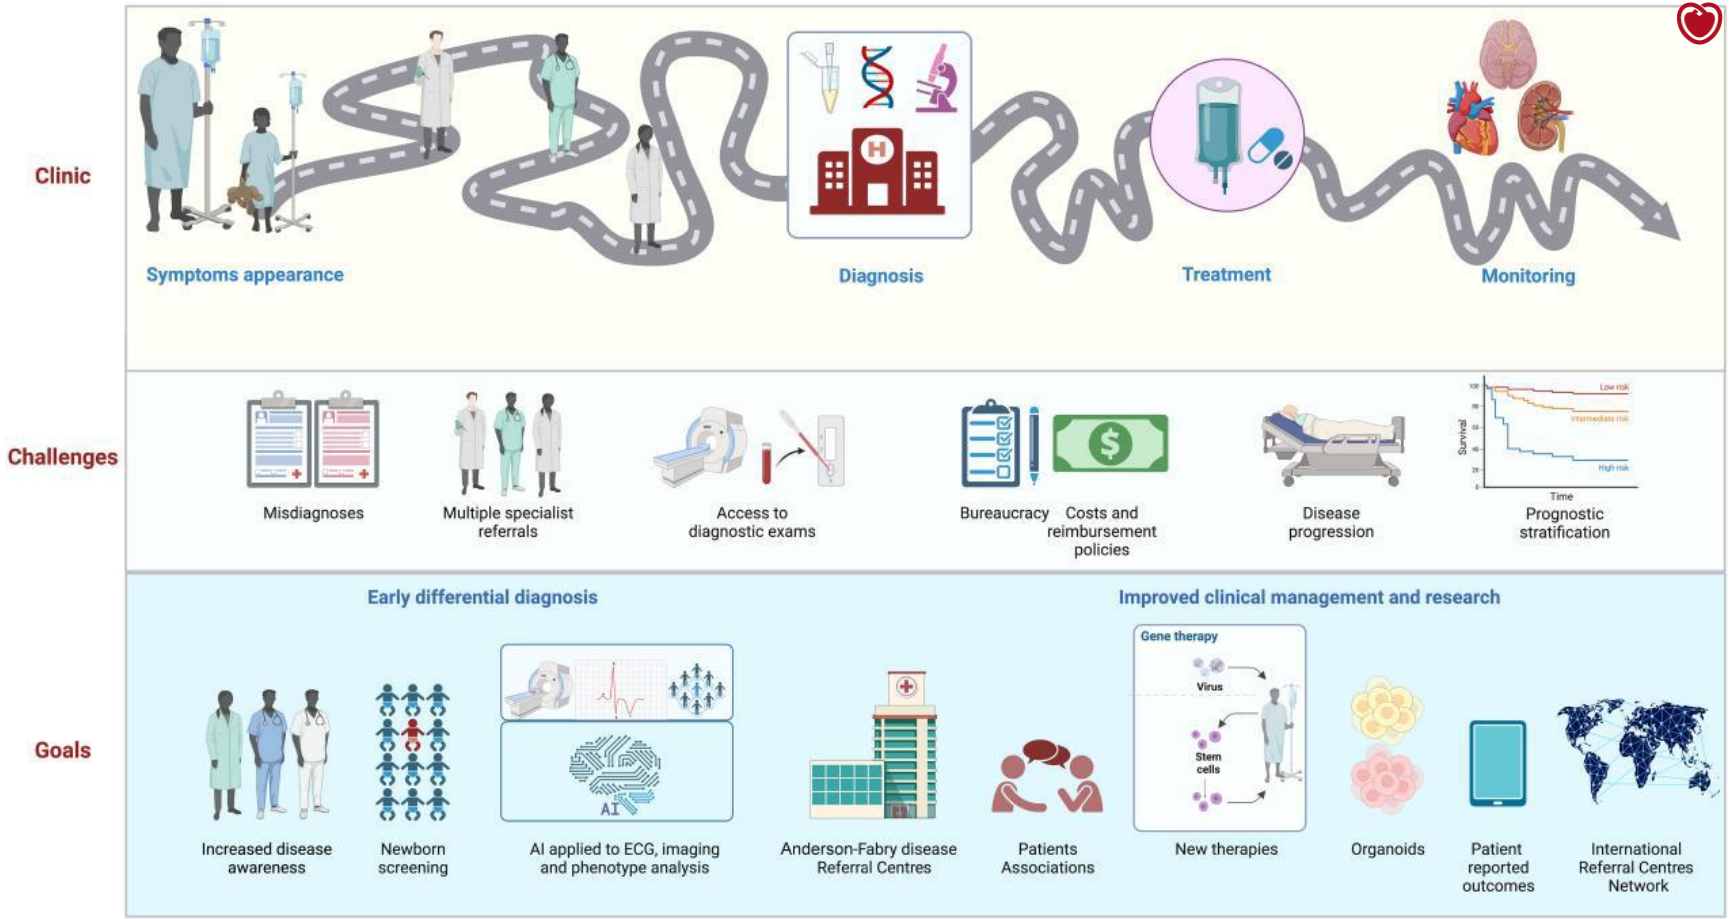
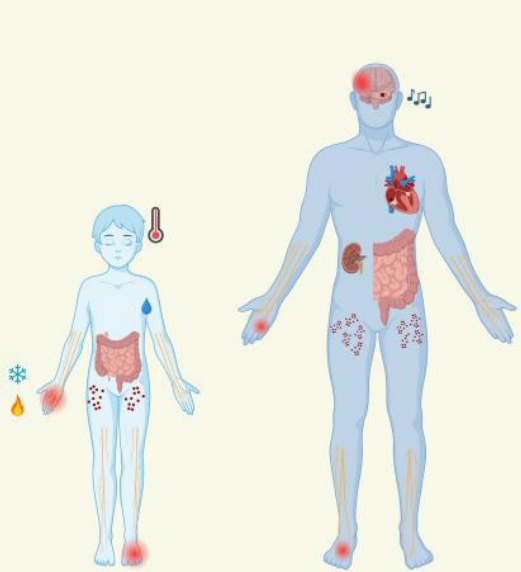
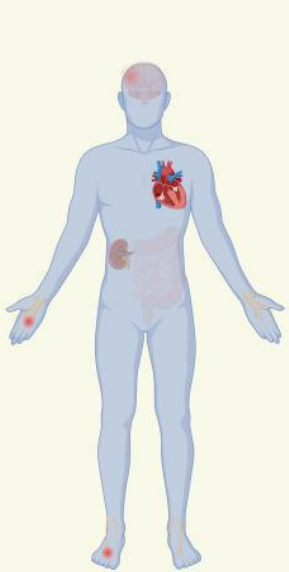


Eur Heart J, ehae148, https://doi.org/10.1093/eurheartj/ehae148



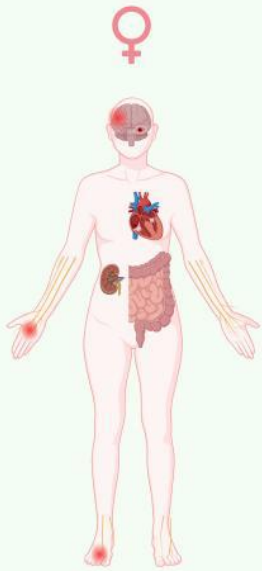
Classic phenotype

- Absent-very low (<5% of normal) alpha-Gal A activity
- High LysoGb3 plasma levels
- Childhood onset with GI symptoms, neuropathic pain, fever, hypohidrosis, angiokeratomas, hearing loss, corneal opacities (cornea verticillata)
- Development of multi-organ (heart, kidneys, CNS) involvement during adolescence and early adulthood



Non-Classic phenotype

- Low (but >5% of normal) alpha-Gal A activity
- Moderately increased LysoGb3 plasma levels
- 3rd-4th decade onset
- Main cardiac phenotype
- Mild involvement of other tissues possible
  - Proteinuria and eGFR reduction
  - GI symptoms
  - Neuropathic pain



Female heterozygotes

- Variable (low to normal) alpha-Gal A activity
- Normal-moderately increased LysoGb3 plasma levels
- Usually 3rd-4th decade onset
- Phenotype ranging from asymptomatic to severe as in affected male relatives due to random X-inactivation, DNA methylation, other epigenetic factors
- Prevalent cardiac phenotype with wide range of other organs involvement

Fabry disease (FD), a rare X-linked lysosomal storage disorder that depletes alpha-galactosidase A (α-GalA), is caused by mutations in the GLA gene. Diminished α-GalA enzyme activity results in the accumulation of Gb3 and lyso-Gb3. The pathophysiology of hypertension in FD is complex and unclear. The storage of Gb3 in arterial endothelial cells and smooth muscle cells is known to produce vascular injury by increasing oxidative stress and inflammatory cytokines as a primary pathophysiological mechanism. In addition, Fabry nephropathy developed, resulting in a decrease in kidney function and contributing to hypertension.

The prevalence of hypertension in patients with FD was between 28.4% and 56%, whereas hypertension in patients with chronic kidney disease ranged between 33% and 79%. A study using 24-hour ambulatory blood pressure monitoring (ABPM) to measure blood pressure (BP) indicated a high prevalence of uncontrolled hypertension in FD. Thus, 24-hour ABPM ought to be considered for FD hypertension assessments.

Appropriate treatment of hypertension is believed to reduce mortality in patients with FD caused by kidney disease, cardiovascular disease, and cerebrovascular disease because hypertension significantly impacts organ damage. Up to 70% of FD patients have been reported to have kidney involvement, and angiotensin-converting enzyme inhibitors and angiotensin receptor blockers prescribed for proteinuria are recommended as first-line therapy with antihypertensive drugs. In conclusion, hypertension should be controlled appropriately, given the different morbidity and mortality caused by significant organ involvement in FD patients.

Key Words: Fabry disease, Hypertension, Enzyme replacement therapy, Angiotensin-converting enzyme inhibitors, Angiotensin receptor blockers

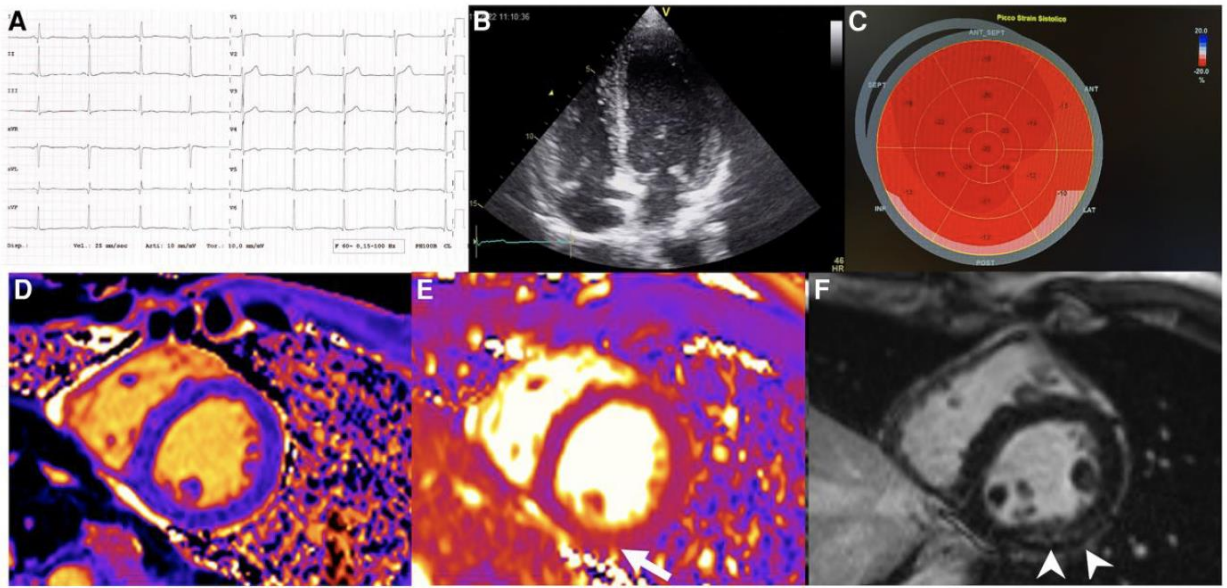

Figure 6 A representative case of a male patient with classic Anderson–Fabry disease and pre-left ventricular hypertrophy cardiac involvement. A 29-year-old male patient carrier of the variant c.859T>C associated with a classic phenotype. Electrocardiogram (*A*) shows sinus rhythm with no signs of left ventricular hypertrophy but repolarization abnormalities in lateral and inferior leads. Transthoracic echocardiogram in apical four-chamber view (*B*) shows normal wall thickness and volume of the left ventricle with initial reduction of longitudinal strain velocities in the inferolateral segments (*C*). Cardiac magnetic resonance shows (*D*) diffusely reduced native T_1 values (905 ± 18 ms, normal reference value 984 ± 18 ms). At T_2 mapping sequences (*E*), a very focal area of high T_2 values in the inferior wall (arrow) can be appreciated, corresponding in post-contrast sequences (*F*) to a thin midwall stria of late gadolinium enhancement (arrowheads)

Prevalence of Fabry disease in a predominantly hypertensive population with left ventricular hypertrophy☆,☆☆

Wim Terryn [a,*], Gert Deschoenmakere [b], Jan De Keyser [c], Wouter Meersseman [d], Wim Van Biesen [e], Brigitte Wuyts [f], Dimitri Hemelsoet [g], Hilbert Pascale [h], Julie De Backer [i], An De Paepe [j], Bruce Poppe [j], Raymond Vanholder [a,e]

Aim: determine the prevalence of FD in an unselected population of everyday clinical practice presenting LVH, defined as a maximal end-diastolic septal or posterior wall thickness ≥13 mm, without exclusion of patients with arterial hypertension or valvular pathology, and using optimal screening methods.

Results: 362 men and 178 women were screened. Six patients were diagnosed with a genetic sequence alteration of the GLA gene.

Conclusions: In a group of unselected patients with LVH, we found a prevalence of Fabry disease of 0.9%. AHT or type of hypertrophy should not be an exclusion criterion for screening for FD.

Challenging the traditional approach for interpreting genetic variants: Lessons from Fabry disease

Dominique P. Germain[1,2] | Thierry Levade[3,4] | Eric Hachulla[5] | Bertrand Knebelmann[6] | Didier Lacombe[7,8] | Vanessa Leguy Seguin[9] | Karine Nguyen[10] | Esther Noël[11] | Jean-Pierre Rabès[2,12]

TABLE 4 Practical recommendations for a more accurate diagnosis of Fabry disease

- Combine insights from disease specific databases and in vitro prediction tools with expert clinical opinion, defining the relative weight of each ACMG criterion.
- Consider the genetic variant as probably benign if its allele total or subpopulation frequency is:
  - Higher than the overall prevalence of FD (0.0125%),
  - Higher than the frequency of the most common pathogenic allele.
- Perform segregation analysis when additional information is required.
- Review the literature and databases periodically to check whether the variant has been reclassified.

Supporting the Diagnosis of Fabry Disease Using a Natural Language Processing-Based Approach

Adrian A. Michalski [1,2,†], Karol Lis [1,3,*,†], Joanna Stankiewicz [1,4], Sylwester M. Kloska [1,5], Arkadiusz Sycz [1,6], Marek Dudziński [1,7], Katarzyna Muras-Szwedziak [8,9], Michał Nowicki [8,9], Stanisława Bazan-Socha [8,10], Michal J. Dabrowski [1,11,‡] and Grzegorz W. Basak [1,3,‡]

This work aimed to create a risk factor scoring system to support physicians in FD diagnosis using real-life data. The authors used a machine learning original approach facilitated by the NLP tool evaluating patients' EHR which can can highlight seemingly imperceptible facts or symptoms that typically elude physicians, preventing proper FD detection.

J. Clin. Med. 2023, 12, 3599. https://doi.org/10.3390/jcm12103599

Key points

- Fabry disease is a multisystemic disease that can affect several organs, resulting in cardiac, neurologic, and renal manifestations.
- Fabry disease is an underestimated disease mainly because of the aspecific phenotipyc variability (HIDDEN DISEASE)
- Suspect Fabry Disease: think metabolic
- Differential diagnosis is crucial in patients with similar clinical-instrumental features
- Several red flags, defined as clinical or instrumental features that help for the diagnosis of a specific disorder, have been proposed to suspect FD.
- New AI diagnostic tools and machine learning algorithms might increase the awareness of FD
- Early diagnosis is linked to early treatment aiming at preventing the disease progression to irreversible organ damage and organ failure.
